- `countLines(text text) → number`
- `sumColumn(path text, table text, col text) → number`

Génération

Génération de la bibliothèque standard

La stdlib AFRILANG (~7971 modules) est générée à partir de scripts Python et de catalogues C++.

Tiers

```
| Tier | Import | Script | Catalogue C++ |
|------|--------|--------|--------------|
| Simple | `import "std/nom"` | `scripts/gen_simple_stdlib.py` | `src/utils/stdlib_catalog.cpp` |
| Medium | `import "std/m/nom"` | `scripts/gen_medium_stdlib.py` | `src/utils/medium_catalog.cpp` |
| Complex | `import "std/c/nom"` | `scripts/gen_complex_stdlib.py` | `src/utils/complex_catalog.cpp` |
```

Packs numérotés (500 modules)

- **giskit** — SIG simple (`gen_simple_stdlib.py`)
- **game2dkit**, **game3dkit**, **gamekit** — kits jeu
- **gisultra**, **rasterultra**, **segultra**, **dataultra**, **datasci**, **vizultra**, **iaultra**, **dbultra**, **gameultra**, **game3dultra** — `gen_complex_stdlib.py`

Workflow après modification

```
# Régénérer un tier (exemple : simple)
python3 scripts/gen_simple_stdlib.py

# Recompiler le compilateur
cd build && cmake .. && make -j$(nproc)

# Synchroniser le site Django
cd web && .venv/bin/python manage.py sync_site
```

Architecture

1. Stub .afr dans stdlib/ — signature des fonctions (IDE, docs). 2. Runtime C++ — runtime/simple_libs.hpp, runtime/medium_libs.hpp, runtime/complex_libs.hpp + headers dédiés (runtime/hex.hpp, runtime/game2d.hpp, ...). 3. Injection — src/utils/stdlib_registry.cpp résout import "std/..." et injecte les modules dans l'AST.

Les modules legacy (io, json, hex, html, email, game2d, ...) ont un header dédié dans runtime/ et ne doivent pas être dupliqués dans simple_libs.hpp.

Tests

afrilang test compile les exemples de référence + un échantillon par famille ultra (segultra, dataultra, giskit, ...).

Partie IX — Gestionnaire de paquets

Guide des paquets AFRILANG

Équivalent pratique de Nimble / Shards pour AFRILANG.

Méthode en 6 étapes

1. Créer — afrilang init / pkg init 2. Déclarer — [dependencies] dans afrilang.toml (version, git, path) 3. Synchroniser — pkg sync (index distant) 4. Installer — pkg install (respecte afrilang.lock s'il existe) 5. Tester — pkg test / afrilang test 6. Publier — pkg publish (+ --remote si registre)

Guide web détaillé (bilingue) : /docs/package-manager/.

Fichiers projet

```
| Fichier | Rôle |
|---------|------|
| `afrilang.toml` | Métadonnées + `[dependencies]` |
| `afrilang.lock` | Versions exactes installées (source de vérité pour `install`) |
| `vendor/` | Copies locales des paquets |
| `manifest.toml` | Métadonnées d'un **paquet** (bibliothèque) |
| `packages/index.json` | Index local |
| `packages/remote-index.json` | Index distant (`pkg sync`) |
```

Créer un projet ou un paquet

```
afrilang init mon_app              # application
afrilang init mon_lib --lib        # alias de pkg init
afrilang pkg init mon_lib          # paquet bibliothèque
cd mon_lib && afrilang pkg test    # self-vendor + tests/
afrilang doc .                     # docs/api/
```

Dépendances

Registre (local ou distant)

```
[dependencies]
math = "0.1.0"
strings = "^0.1.0"
```

```
afrilang pkg sync                  # télécharge remote-index.json
afrilang pkg add math              # local packages/ ou clone via url/method
afrilang pkg install
afrilang pkg update
```

Si le paquet n'est pas dans packages/<name> mais apparaît dans l'index avec "method":"git" + "url", AFRILANG clone comme Nimble (cache sous packages/.cache/).

Voir le modèle : packages/remote-index.example.json.

Semver

```
| Range | Signification |
|-------|---------------|
| `1.2.3` | `actual >= 1.2.3` (compat historique) |
| `^1.2.3` | `>= 1.2.3` et `< 2.0.0` |
| `~1.2.3` | `>= 1.2.3` et `< 1.3.0` |
```

Git

```
[dependencies]
mylib = { git = "https://github.com/org/mylib.git", tag = "v0.1.0" }
```

```
afrilang pkg add mylib --git https://github.com/org/mylib.git --tag v0.1.0
```

Path (développement local)

```
[dependencies]
mylib = { path = "../mylib" }
```

```
afrilang pkg add mylib --path ../mylib
```

Transitivité & conflits

install / update résolvent les deps des manifest.toml récursivement. Si deux contraintes sur le même nom sont incompatibles → erreur de conflit.

Install vs update

- `pkg install` — si `afrilang.lock` existe, installe **exactement** le lock ; sinon résout depuis le toml et écrit le lock.
- `pkg update` — ignore les pins du lock, re-résout depuis les ranges du toml, réécrit le lock.

Publier

Local

```
afrilang pkg publish ./mon_lib
afrilang pkg list
```

Distant (style Nimble)

```
export AFRILANG_PACKAGE_GIT_URL=https://github.com/vous/mon_lib
export AFRILANG_REGISTRY_TOKEN=...          # optionnel
export AFRILANG_REGISTRY_PUBLISH_URL=...    # optionnel
afrilang pkg publish ./mon_lib --remote
```

Écrit registry-entry.json, affiche la recette d'ajout au registre, et POST si un token est défini.

Variables utiles :

```
| Variable | Rôle |
|----------|------|
| `AFRILANG_REGISTRY_URL` | URL de l'index JSON (`pkg sync`) |
| `AFRILANG_REGISTRY_PUBLISH_URL` | Endpoint POST publish |
| `AFRILANG_REGISTRY_TOKEN` | Bearer token |
| `AFRILANG_PACKAGE_GIT_URL` | URL git du paquet pour la recette |
```

Imports

```
import pkg/math/math
```

Partie X — Outils (LSP, VS Code, WASM)

afrilang lsp — diagnostics, hover, définition, complétion EN/FR.

Extension VS Code

AFRILANG — extension VS Code / Cursor / VSCodium

Coloration syntaxique, diagnostics, complétion LSP, formatage et exécution de fichiers .afr.

Installation (utilisateurs)

Depuis l'éditeur : Extensions → rechercher AFRILANG → Install

```
code --install-extension afrilang.afrilang      # VS Code
codium --install-extension afrilang.afrilang    # VSCodium
# Cursor : même marketplace que VS Code
```

Compilateur requis

L'extension appelle afrilang pour le LSP et l'exécution. Compilez AFRILANG puis configurez :

```
{
  "afrilang.serverPath": "/chemin/vers/AFRILANG/build/afrilang"
}
```

Installation locale (développeurs)

```
cd vscode-afrilang
./install.sh
```

Puis Developer: Reload Window.

Publication (mainteneurs)

Voir PUBLISHING.md.

```
cd vscode-afrilang
npm install
./publish.sh          # crée afrilang-1.4.0.vsix (+ publish si VSCE_PAT/OVSX_PAT)
```

Tag Git optionnel : git tag vscode-v1.4.0 && git push origin vscode-v1.4.0 déclenche le workflow CI.

Open VSX (VSCodium / Cursor)

Après publication, l'extension est disponible sur Open VSX :

```
codium --install-extension afrilang.afrilang
```

Configuration

```
| Paramètre | Défaut | Description |
|-----------|--------|-------------|
| `afrilang.serverPath` | `afrilang` | Chemin vers l'exécutable (absolu si hors PATH) |
| `afrilang.trace.server` | `off` | Trace LSP dans le panneau « AFRILANG LSP » |
```

Exemple settings.json :

```
{
  "afrilang.serverPath": "/home/user/AFRILANG/build/afrilang",
  "editor.formatOnSave": true,
  "[afrilang]": { "editor.tabSize": 4 }
}
```

Fonctionnalités

- **Diagnostics** — erreurs de compilation en temps réel (soulignés rouges)
- **Complétion** — mots-clés FR/EN + Phase 6 (`enum`, `match`, `nothing`, ...)
- **Formatage** — `Shift+Alt+F` ou format on save via LSP
- **Exécuter** — bouton ▶ dans l'éditeur ou commande *AFRILANG: Exécuter le fichier*
- **Vérifier** — *AFRILANG: Vérifier le fichier* (`afrilang check`)
- **Débugger** — *AFRILANG: Débugger le fichier* (adaptateur DAP + GDB, types Afrilang dans Variables)
- **Config debug** — *AFRILANG: Initialiser la config debug* → `launch.json` pour F5
- **Icône** — carte d'Afrique pour les fichiers `.afr`

Icône + coloration des fichiers `.afr`

Le workspace active le thème d'icônes AFRILANG (afrilang-icons) : les .afr affichent la carte d'Afrique. La grammaire TextMate colore mots-clés, types, chaînes, etc.

Important — Cursor Agents Window (Glass) La coloration et les icônes d'extensions ne s'appliquent pas dans la vue Agents (bug Cursor connu). Ce n'est pas un défaut de l'extension AFRILANG.

Pour voir couleurs + logo :

1. Ctrl+Shift+P → Cursor: Open or Focus Editor Window (cursor.openOrFocusEditorWindow) — quitte Glass / Agents 2. Ouvrir examples/hello.afr dans cet éditeur classique 3. Barre d'état (bas à droite) = AFRILANG 4. File Icon Theme = AFRILANG

Réinstallation si besoin :

```
cd vscode-afrilang && ./install.sh
# ou :
cursor --install-extension ./afrilang-1.4.0.vsix
```

Puis Developer: Reload Window.

Commandes

- `AFRILANG: Exécuter le fichier`
- `AFRILANG: Vérifier le fichier`
- `AFRILANG: Redémarrer le serveur LSP`

WASM

Compatibilité WASM (wasm32)

AFRILANG peut cibler wasm32 via Emscripten (afrilang run fichier.afr --target wasm32).

Fonctionne en WASM

```
| Domaine | Modules / features |
|---------|-------------------|
| Langage de base | variables, fonctions, boucles, `if`, listes, maps |
| POO | classes, héritage, interfaces |
| Stdlib core | `json`, `str`, `math`, `collections`, `args`, `path`, `log` |
| Async | `std/async` — `sleep`, coroutines (Emscripten) |
| Démos CI | `examples/tier8_demo.afr`, `examples/tier8_stdlib.afr` |
```

Natif uniquement (pas WASM)

```
| Domaine | Raison |
|---------|--------|
| `std/ui`, SDL2 | pas de fenêtre native en navigateur |
| `std/game2d`, `std/game3d` | OpenGL / SDL |
| `std/http` (sync) | sockets système |
| `std/fs`, `std/io` fichiers | accès disque limité en WASM |
| `std/thread` | threads POSIX |
| `std/gamenet` UDP | sockets réseau |
| Packs ultra lourds | compilation/link très longue ; tester en natif |
```

Playground JS (`compile-js`)

Sous-ensemble élargi (Vague 3) : say, assign/set, if/while/repeat/for, fonctions + appels + return. Toujours exclus : imports, classes, async, UI, tests.

Recommandation

- **Playground / CI WASM** : petits programmes sans SDL/OpenGL ; stdlib `str`/`math`/`json` OK.
- **Jeux, SIG, data science** : cible `native` ou `linux-arm64`.

- fmt
- lint
- debug (GDB)
- explain

Partie XI — Site web, playground, mobile

```
afrilang serve  # http://127.0.0.1:8080
```

AFRILANG Web — Django + PostgreSQL + Bootstrap + Tailwind

Site officiel dynamique pour l'écosystème AFRILANG.

Stack

```
| Couche | Technologie |
|--------|-------------|
| Backend | **Django 5** |
| Base de données | **PostgreSQL 16** |
| UI | **Bootstrap 5** + **Tailwind CSS** (préfixe `tw-`) |
| Compilateur | binaire `afrilang` (subprocess) |
```

Démarrage rapide

```
# 1. PostgreSQL
cd web
docker compose up -d

# 2. Python
python3 -m venv .venv
source .venv/bin/activate
pip install -r requirements.txt
cp .env.example .env

# 3. Tailwind (optionnel — CSS minimal inclus)
npm install && npm run build:css

# 4. Django
python manage.py migrate
python manage.py seed_data
python manage.py sync_packages
python manage.py createsuperuser   # optionnel
python manage.py runserver
```

Ouvrir http://127.0.0.1:8000

Pages

- `/` — Accueil (stats, paquets DB, exemples)
- `/explore/` — Capacités (modèle `Capability`)
- `/docs/` — Documentation
- `/packages/` — Registre PostgreSQL + recherche
- `/playground/` — Éditeur + API run/fmt
- `/benchmarks/` — Graphiques compile/exec (Chart.js)
- `/showcase/` — Galerie projets GitHub
- `/admin/` — Administration Django

API REST

```
| Endpoint | Méthode | Description |
|----------|---------|-------------|
| `/api/run/` | POST | `{ "source": "..." }` → exécution native |
| `/api/compile/js/` | POST | Transpile vers JavaScript (exécution navigateur) |
| `/api/build/wasm/` | POST | Module WASM pour le navigateur (Emscripten serveur) |
| `/api/wasm/<id>/module.js` | GET | Artefact WASM de session |
| `/api/run/wasm/` | POST | Exécution WASM serveur (emscripten requis) |
| `/api/fmt/` | POST | Formatage |
| `/api/packages/` | GET | Liste JSON des paquets |
```

Les runs playground sont enregistrés dans PlaygroundRun (PostgreSQL).

Variables d'environnement

Voir .env.example :

- `DATABASE_URL` — PostgreSQL
- `AFRILANG_BIN` — chemin vers le compilateur
- `AFRILANG_ROOT` — racine du repo
- `PLAYGROUND_WASM_DIR` — sessions WASM temporaires (défaut: `web/tmp/wasm_sessions`)

Compilateur WASM client (optionnel)

Pour exécuter la compilation dans le navigateur sans appeler /api/compile/js :

```
# Nécessite Emscripten (emsdk)
./scripts/build_wasm_compiler.sh
# → web/static/compiler/afrilang-compiler.js
```

Commandes utiles

```
python manage.py sync_packages   # packages/index.json → PostgreSQL
python manage.py sync_benchmarks # scripts/benchmark.sh → SiteMetric
python manage.py seed_data       # exemples + capacités
```

Ancien site statique

Le dossier site/ (serveur C++ afrilang serve) reste disponible. Ce projet Django le remplace pour la production avec base de données.

Mobile

AFRILANG Mobile (Flutter)

Application mobile qui reproduit le frontend du site web et consomme le même backend Django (web/).

Prérequis

- Flutter 3.22+ (`flutter doctor`)
- Backend web avec le **venv** (Django n’est pas installé globalement) :

```
cd web
source .venv/bin/activate
python manage.py runserver 0.0.0.0:8000
```

Si .venv n’existe pas encore :

```
cd web
python3 -m venv .venv   # ou: uv venv .venv
source .venv/bin/activate
pip install -r requirements.txt
```

Lancer l'app

```
cd mobile/afrilang
flutter pub get
flutter run
```

URL du backend

```
| Cible | Base URL |
|--------|----------|
| Émulateur Android | `http://10.0.2.2:8000` (défaut) |
| iOS Simulator / desktop / Chrome | `http://127.0.0.1:8000` |
| Téléphone physique | IP LAN, ex. `http://192.168.1.10:8000` |
```

Override :

```
flutter run --dart-define=AFRILANG_API_BASE=http://192.168.1.10:8000
```

Icône d'application

L'icône launcher utilise le logo Afrique AFRILANG (plus le logo Flutter).

```
cd mobile/afrilang
python3 tool/generate_app_icons.py
```

Sur Android, le fond de l'icône adaptive est transparent pour laisser apparaître la silhouette Afrique (le launcher impose toujours un masque cercle/squircle). Sur iOS, Apple impose un carré arrondi opaque — logo Afrique sur fond navy.

- Accueil (hero, stats, features, paquets certifiés, CTA)
- Documentation (pages FR/EN + blocs code / callouts)
- Paquets + détail
- Exemples + Run
- Stdlib (cœur / expérimental) + détail API
- Playground (Run / Format / Check)
- Tutoriel interactif, releases, FR/EN, mode sombre

API Django utilisée

Préfixe : /api/mobile/

- `GET bootstrap/`, `home/`, `docs/`, `docs/<slug>/`
- `GET packages/`, `packages/<name>/`, `examples/`, `stdlib/`, `stdlib/<name>/`
- `GET tutorial/`, `tutorial/<step>/`, `releases/`
- `POST run/`, `fmt/`, `check/` (CSRF exempt, rate-limité comme le playground web)

Les exemples détaillés utilisent aussi GET /api/examples/<slug>/.

Structure

```
lib/
  config/api_config.dart
  services/api_client.dart
  state/app_state.dart
  theme/afrilang_theme.dart   # Plus Jakarta Sans + JetBrains Mono, #1d4ed8
  widgets/common.dart         # code panel, hero mesh, fade-ins
  screens/…
```

Partie XII — Catalogue d'exemples

```
afrilang run examples/NOM.afr
```

88 fichiers

- CodeGenerator → C++ / g++
- Sandbox + cache

```
list→vector  text→string  number→double
ask as number → getline + stod
say/+ → str::toString/concat
```

Partie XIV — Roadmap, contribution, licence

Roadmap AFRILANG

Objectif : rapprocher AFRILANG d'un produit langage de type Nim / Crystal (haut niveau → natif + écosystème paquets), sans prétendre cloner 15 ans d'adoption d'un coup.

Vague 1 — Parité écosystème (livrée)

Inspiré de Nimble et Shards :

• [x] `pkg init` — scaffold paquet (`manifest.toml`, module, tests, README)
• [x] Deps **git** / **path** dans `afrilang.toml`
• [x] `afrilang.lock` comme source de vérité pour `pkg install`
• [x] `pkg update` — re-résolution + régénération du lock
• [x] Semver `^` / `~`
• [x] `afrilang init` enrichi (`.gitignore`, README, `tests` avec `assert`) + `--lib`
• [x] `afrilang test` découvre `tests/**/*.afr` ; `--examples` pour la suite demos
• [x] Docs : ce roadmap, `PKG.md`, `CORE_STDLIB.md`
• [x] `afrilang doc <dir>` → `docs/api/`

Vague 2 — Registre distant (livrée)

Modèle nim-lang/packages (url + method: git) :

• [x] Téléchargement de paquets depuis l'index distant si absent du registre local
• [x] `pkg sync` enrichit `list` / `search` / `lookup` via `remote-index.json`
• [x] `pkg publish --remote` — recette `registry-entry.json` + POST si `AFRILANG_REGISTRY_TOKEN`
• [x] Résolution transitive multi-niveaux + détection de conflits de versions
• [x] Index enrichi (`url`, `method`, `tags`, `license`, `web`)
• [x] `pkg test` — boucle auteur (self-vendor + tests/)

Vague 3 — Profondeur & cibles (livrée)

• [x] Qualité du **core stdlib** : `docs/STDLIB_API.md` + `tests/stdlib/*.afr`
• [x] UX stubs : hover LSP core vs experimental ; site stdlib **core** par défaut (`?experimental=1`)
• [x] WASM / JS : sous-ensemble documenté (`WASM_COMPAT.md`) + `examples/tier8_stdlib.afr` ; playground JS avec fonctions/`for`
• [x] Batterie specs : `afrilang test --specs` (`tests/specs` + `tests/stdlib`)
• [x] Site packages : tags / repo / README / recherche (`sync_packages`, détail paquet)

Hors roadmap (non codable ici)

Communauté, libs tierces, adoption — progressent avec le registre distant + usage réel.

Contribution

PR bienvenues sur https://github.com/MaximeKELI/AFRILANG. Tests dans tests/test_compiler.cpp.

Annexe A — Glossaire

AST
Arbre syntaxique abstrait.

CLI
Interface ligne de commande.

Codegen
Génération C++.

FFI
Appels bibliothèques C.

LSP
Language Server Protocol.

PAHT
Prix d'Achat Hors Taxes.

REPL
Boucle interactive.

Result
Type T or error.

Sandbox
Exécution isolée.

Stdlib
Bibliothèque standard.

WASM
WebAssembly.
